

OS-52 Supplemental: Power BI

With some correct transformations, it was easy enough to flatten the 52 With a View list from the JSON file in Power BI. The data is already shaped well, but we could impute the 10% of missing values as needed for statistical analysis, as in **Figure 1** *Power BI Transformations*:

With that, we can generate powerful reports and visuals for deeper analysis. For example, charting the ratio of trail length and height gain against rated difficulty. This we can easily find the longest-tallest mountain that's still an easier trail.

Figure 2 *Climb vs. Reach in Power BI*

Description: A scatterplot of hiking routes, with route length on the X axis and height gain on the Y axis. The main trend is a linear positive correlation, with Easier routes at the low end, and Harder routes at the high end. The longest-highest-easiest mountain is Mt. Monadnock.

We can also map the peaks with latitude and longitude data and color them according to difficulty, or zoom in to see if the GPS co-ordinates match the map data, as seen in **Figure 3** *Map of Peaks by Difficulty*, and **Figure 4** *Chocorua Zoom*.

Description: **F.4** A map of New Hampshire’s 52 With a View, colored by difficulty rating. The isolated mountain, the only one in Southern New Hampshire, is Monadnock. **F.5** a closer inspection of the area around Mt. Chocorua. The northern peak is “Middle Sister” and the southern peak is the listed 52WAV summit co-ordinates. The middle peak is from Azure Maps data.
